## Is It Safer Than Measles?

### 1. WHAT ARE SIDE EFFECTS OF THE MMR VACCINE?

Common side effects of the MMR vaccine include fever, mild rash, and swelling of glands in the cheeks or neck.<sup>1</sup> A more serious side effect is seizure, which occurs in about 1 in 640 children vaccinated with MMR<sup>2</sup>—about five times more often than seizure from measles infection.<sup>3</sup>

H

Seizures from the MMR vaccine occur 5x more often than measles-related seizures.

The World Health Organization (WHO) states that serious allergic reactions to the vaccine occur in about 1 in 100,000 doses.<sup>4</sup> However, other severe side effects include deafness, long-term seizures, coma, lowered consciousness, permanent brain damage, and death.<sup>1</sup> While the Centers for Disease Control and Prevention (CDC) states that these side effects are rare, the precise numbers are unknown.<sup>1</sup> Additionally, the manufacturer’s package insert states, “M-M-R II has not been evaluated for carcinogenic or mutagenic potential, or potential to impair fertility.”<sup>5</sup>

No safety studies for:

Cancer

Genetic mutations

Impaired fertility

### 2. HOW ARE RISKS OF VACCINE SIDE EFFECTS MEASURED?

Methods to measure vaccine risks include surveillance systems, clinical studies, and epidemiological studies.

### 3. HOW ACCURATE IS SURVEILLANCE OF ADVERSE EVENTS FROM THE MMR VACCINE?

The government tracks reported cases of vaccine side effects through the Vaccine Adverse Event Reporting

System (VAERS). Approximately 40 cases of death and permanent injury from the MMR vaccine are reported to VAERS annually.<sup>6</sup> However, VAERS is a passive reporting system—authorities do not actively search for cases and do not actively remind doctors and the public to report cases. These limitations can lead to significant underreporting.<sup>7</sup> The CDC states, “VAERS receives reports for only a small fraction of actual adverse events.”<sup>8</sup> Indeed, as few as 1% of serious side effects from medical products are reported to passive surveillance systems,<sup>9</sup> and as few as 1.6% of MMR-related seizures are reported to VAERS.<sup>10</sup> In addition, VAERS reports are not proof that a side effect occurred, as the system is not designed to thoroughly investigate all cases.<sup>11</sup> As a result, VAERS does not provide an accurate count of MMR vaccine side effects.

### 4. HOW ACCURATE ARE CLINICAL TRIALS OF THE MMR VACCINE?

The CDC states, “Prelicensure trials are relatively small—usually limited to a few thousand subjects—and usually last no longer than a few years. Prelicensure trials usually do not have the ability to detect rare adverse events or adverse events with delayed onset.”<sup>7</sup> Since measles is fatal in about 1 in 10,000 cases and results in permanent injury in about 1 in 80,000 cases,<sup>3</sup> a few thousand subjects in clinical trials are not enough to prove that the MMR vaccine causes less death and permanent injury than measles (Fig. 1). In addition, the lack of adequate clinical trials of the MMR vaccine resulted in the manufacturer’s package insert data to be reliant on passive surveillance for rates of MMR-related neurological adverse reactions, permanent disability, and death.<sup>5</sup>

**Figure 1:** There are not enough subjects in clinical trials to prove that the MMR vaccine poses less risk than measles.

## 5. HOW ACCURATE ARE EPIDEMIOLOGICAL STUDIES OF THE MMR VACCINE?

Epidemiological studies are hindered by the effects of chance and possible confounders—additional factors that could conceivably affect the groups being studied. For example, there is a well-known 2002 Danish study published in the *New England Journal of Medicine* involving about 537,000 children that looked for an association between the MMR vaccine and certain adverse events.<sup>12</sup> The raw data in the study was adjusted, in an attempt to account for potential confounders, and the study found no association between the MMR vaccine and the adverse events. However, because there is no evidence that the estimated confounders used to adjust the raw data were actually confounders, the study did not rule out the possibility that the MMR vaccine increases the risk of an adverse event that leads to permanent injury by up to 77%. Consequently, the study did not rule out the possibility that such adverse events might occur up to four times more often than death from measles: 1 in 2,400 compared to 1 in 10,000 (Fig. 2 and Table 1). The range of possibilities found in the study, between the adjusted data and the raw data, makes the result inconclusive; even large epidemiological studies are not

accurate enough to prove that the MMR vaccine causes less death or permanent injury than measles.

## 6. IS THE MMR VACCINE SAFER THAN MEASLES?

It has not been proven that the MMR vaccine is safer than measles. The vaccine package insert raises questions about safety testing for cancer, genetic mutations, and impaired fertility. Although VAERS tracks some adverse events, it is too inaccurate to measure against the risk of measles. Clinical trials do not have the ability to detect less common adverse reactions, and epidemiological studies are limited by the effects of chance and possible confounders. Safety studies of the MMR vaccine are particularly lacking in statistical power. A review of more than 60 MMR vaccine studies conducted for the Cochrane Library states, “The design and reporting of safety outcomes in MMR vaccine studies, both pre- and post-marketing, are largely inadequate.”<sup>13</sup> Because permanent sequelae (aftereffects) from measles, especially in individuals with normal levels of vitamin A, are so rare,<sup>3</sup> the level of accuracy of the research studies available is insufficient to prove that the vaccine causes less death or permanent injury than measles.

**Figure 2:** A 2002 Danish study did not rule out the possibility that the MMR vaccine can cause an adverse event leading to permanent injury four times more often than measles can be fatal.

**Table 1: Statistical Analysis of an Epidemiological Study with Over Half a Million Children**

RR = Relative risk  
 $(\text{risk in group vaccinated with MMR}) \div (\text{risk in group not vaccinated with MMR})$

CI = Confidence interval  
 (possible range of RR due to effects of chance)

Adjusted RR reported in study  
 = 0.92 (95% CI, 0.68 to 1.24)

Unaltered RR recorded in study  
 $(263/1,647,504) \div (53/482,360)$   
 = 1.45 (95% CI, 1.21 to 1.77)

Potential RR = 1.77  
 (potential 77% greater risk than unvaccinated group risk)

Unvaccinated group risk recorded in study  
 = 53 in 97,000

77% of 53 in 97,000  
 = 1 in 2,400 additional risk in group vaccinated with MMR
